

Agentic order management

Background

Fixed-line order fulfillment is exposed to frequent, late-detected failures across different layers, creating a need for proactive AI-driven detection, and guided resolution along with reactive manual handling. Operations teams in EOC largely rely on manual analysis, siloed monitoring, and manual root-cause investigation, and looking for a solution to:

- 1. Detect failed orders and error code from EOC orders list
- 2. Correlate quickly towards the most relevant resolution actions
- 3. Initiate communication towards operations team for action

Solution architecture and components

Using AI technology, the proposal is to increase the efficiency in reduction of order fallout process, improving time to take corrective measures for failed orders, self-healing minor errors as much possible and keeping Human-in-the-loop for the verification of the actions in operations team. An agentic AI procedure that helps the operations team in EOC automatic tasks and reduce manual effort for a potential e2e scalable solution.

Components

LLM, embedding, indexing, and similarity search components
